

Stephania crebra

Stephania crebra is a herbaceous perennial vine in the genus *Stephania* of the family Menispermaceae. It is native to Southeast Asia and was first described in Thailand in 1988 by L. L. Forman. It is one of 15 *Stephania* found only in northern Thailand, specifically in the province of Chiang Mai. It has leaves 12–17 cm (4.7–6.7 in) long and 9–16 cm (3.5–6.3 in) wide. It resembles *Stephania reticulata* but *S. crebra* has larger flowers but smaller drupes and endocarps.[1]
